Description

[0001] This invention relates to a paired optically variable device with paired optically variable pigments and inks, paints and foils incorporating the same and a method.

[0002] Color from interference thin films is found in nature in fish scales, mother of pearl, etc. Naturally occurring mica, oil slicks and soap bubbles all display to some degree a level of iridescence. This iridescence or change in color as the viewing angle is changed, is a direct result of light reflecting from parallel interfaces from single or multilayer thin films. In general, the larger the refractive index difference across the interface(s) the greater the color effect. Color results from the interference of light. Maximum destructive reflective light interference occurs when the thickness of the layers are an odd number of quarter waves whereas maximum constructive light interference occurs when the thickness of the layers are an even number of quarter waves. Iridescent coatings which are called nacreous pigments when broken into small platelets are described in U.S. Patent Nos. 3,087,828 and 3,123,490. These nacreous pigments are composed of single layer or multilayers in the optical thicknesses ranging from 10-100 nanometers typically prepared by vacuum deposition processes. These nacreous pigments are white or silvery and have very low colour saturation regardless of the viewing orientation. Colour is due mainly to simple Fresnel light reflection, scattering and/or absorption. Within many applications, it is desirable to achieve greater colour saturation, i.e., chroma, than that can be achieved with nacreous pigments. In addition to chroma, there is a need for different colours and different colour combinations which can be generated by using optically variable pigments. There is a particular need for such a multitude of colours for numerous anti-counterfeiting applications as well as other applications.

[0003] In US 5,009,486, the two optical structures disclosed have a common layer which provides the optical signature for both devices.

[0004] In general, it is an object of the present invention to provide a paired optically variable device and method utilizing paired optically variable pigments to achieve different colour combinations which can be utilized in inks, paints and foils.

[0005] According to a first aspect of the invention there is provided a paired optically variable article comprising a substrate having a first surface, wherein first and second optical devices are carried by said first surface, at least one of the first and second optical devices being optically variable and forming a pair carried by the first surface of the substrate in spaced-apart positions on the first surface of the substrate to permit viewing at the same time by the human eye, said first and second optical devices having the same matching colour at one angle of incidence between 0° and 90° for a colour match angle and being without colour match at all other angles of incidence, the first and second optical devices being pigments, specular foils or multilayer thin film interference stacks.

[0006] According to a second aspect of the invention there is provided a method for creating a coloured reflectance from a substrate, said substrate having a first surface and first and second optical devices formed of layers carried by said first surface, at least one of said first and second optical devices being optically variable and forming a pair carried by the first surface of the substrate in spaced apart positions on the first surface of the substrate to permit viewing at the same time by the human eye, forming said at least one optically variable device so it has one colour at one angle of incidence that is the same colour at the same angle of incidence as the colour of the second optical device, illuminating the paired optical devices from a light source whereby the pair of optical devices reflect the same colour at said one angle of incidence between 0° and 90° and being without colour match at all other angles of incidence, the first and second optical devices being pigments, specular foils or multilayer thin film interference stacks.

[0007] In the accompanying drawings:

Figure 1 is a plan view of a paired optically variable device incorporating paired optically variable pigments incorporating the present invention.

Figure 2 is a cross-sectional view taken along the line 2-2 of Figure 1.

Figure 3 is a graphical representation of the examples shown in Tables I, II and III and showing the matching of colours of paired designs at 10° under Illuminant A.

Figure 4 is a graphical representation similar to that shown in Figure 3 but showing the divergence of colours of paired designs at 45° under Illuminant A.

Figure 5 is a graphical representation of the examples shown in Tables IV, V and VI showing the divergence of colors at 10° under Illuminant A.

Figure 6 is a graphical representation of the examples in Tables IV, V and VI at 45° showing the matching of colors of paired designs under Illuminant A.

Figure 7 is a graphical representation of the examples shown in Tables VII, VIII and IX showing the matching of colors of paired designs at 10° under Illuminant C.

Figure 8 is a graphical representation of the examples shown in Tables VII through IX showing divergence of colors of paired designs at 45° under Illuminant C.

Figure 9 is a graphical representation of the examples shown in Tables X, XI and XII showing divergence of colors

of paired designs at 10° under Illuminant C.

Figure 14 is a graphical representation of the examples in Tables XVI-XVIII showing the matching of colors of paired designs at 45° under Illuminant F.

Figure 15 is a cross-sectional view of a paired optically variable device incorporating the present invention utilizing a symmetric metal dielectric interference stack.

Figure 16 is a cross-sectional view of a paired optically variable device having an all dielectric symmetrical interference stack.

Figure 17 is a plan view of a pair of paired optically variable devices incorporating the present invention and utilizing paired optically variable pigments.

Figure 18 is a plan view of a paired optically variable device incorporating the present invention in which a symbol is incorporated therein and is not visible to the human eye at a predetermined angle of incidence.

Figure 19 is a plan view similar to Figure 18 but viewed at a different angle of incidence which makes visible the "SICPA" symbol incorporated in the paired optically variable device.

Figure 20 is a cross-sectional view taken along the line 20-20 in Figure 19.

Figure 21 is a plan view of a paired optically variable device incorporated into dot matrix foils with a symbol incorporated therein and having an angle of incidence in which the symbol is invisible.

Figure 22 is a view similar to Figure 21 with a different angle of incidence so that the symbol incorporated therein is visible.

Figure 23 is a cross-sectional view taken along the line 23-23 of Figure 22.

[0008] In general, the optically variable device of the present invention is for use or viewing under incident light and is comprised of a substrate having first and second surfaces. First and second optical devices are carried by the first surface of the substrate in first and second spaced apart portions on the first surface to permit viewing at the same time by a human eye. A first optically variable pigment is disposed in the first optical device and a second optical pigment is disposed in the second device. The first and second optical devices have substantially the same color at one angle of incidence and colors different from each other at all other angles of incidence.

[0009] More in particular as shown in Figure 1 of the drawings, the optically variable device 11 consists of a substrate 12 provided with first and upper surface 13 and a second or lower surface 14 as shown in Figure 2. The substrate 12 can be flexible or rigid and can be formed of any suitable material such as paper, plastic, cardboard, metal and the like. The substrate 12 can be opaque or transparent. Paired optically variable pigments 16 in a polymeric binder are disposed on one of the surfaces as for example on the first or top surface 13 as shown in Figure 2 so that they are not superposed but are lying in spaces which are physically separated from each other on the plane of the surface 13. When the optically variable device is viewed the paired optically variable pigments 16 can be viewed simultaneously.

[0010] Thus as shown in Figure 1, the device 11 has paired optically variable pigments 16 provided in a first optically variable device or pattern 17 and also in a second optically variable device or pattern 18. The first and second patterns 17 and 18 do not overlap and are spaced apart but are disposed adjacent to each other and as shown in Figure 2 in an abutting relationship. The first pattern 17 is in the form of a rectangle or square and is disposed within a recess 19 formed by the second pattern 18 also being in the form of a rectangle or square to form a border or frame that surrounds the first pattern 17.

[0011] The first optically variable device 17 or the first pattern 17 is provided with a first pigment formed of optically variable flakes 21 constructed in the manner hereinbefore described to provide a first color shift with angle. The second optically variable device or second pattern 18 is provided with a second pigment formed of optically variable flakes 22 also constructed in the manner hereinafter described and providing a second color shift with angle. As shown in Figure 2, the pigments 21 and 22 are disposed of in solidified liquid vehicles 23 and 24 respectively of a conventional type so that the optically variable devices 17 and 18 can have the desired characteristics. For example if an ink is the resulting product, a conventional ink vehicle is utilized whereas if a paint is the desired product, a paint vehicle of a suitable type is utilized.

[0012] In the first and second pigments or flakes 21 and 22 utilized, it is important that the two pigments have the same color at one angle of incidence of light and have different colors at all other angles of incidence of light. Thus by way of example, the pigments 21 and 22 can be constructed so that at a 10° angle of incidence of light, the two pigments

have the same color but at any other higher angle of incidence the two optically variable pigments 21 and 22 will have different colors which for example at 45° are markedly different. Conversely, the pigments 21 and 22 could be constructed so that they have the same color at a different angle as for example an angle of 45° but have different colors at all other angles of incidence. However, it should be understood that other color matches can be found from 0°-90°.

Thus by way of example with the device 11 shown in Figure 1, the pigments 21 and 22 at an angle of incidence of about 10° would have the same color or a matched color, as for example, green and another color, magenta at another angle of about 45° for the first device 17 and the color blue for the second device 18. Thus, it can be seen there is a dramatic color shift differential when shifting from 10° to 45° the angle of incidence of the paired optically variable device 11.

[0013] In one embodiment of the invention as shown in Figure 1, the inner first optically variable device (OVD) 17 had the following characteristics with respect to the outer or second optically variable device (OVD) 18.

OUTER OVD 18		INNER OVD 17	
L*	54.91	L*	42.69
a*	-32.45	a*	19.29
b*	-11.48	b*	-51.25

[0014] The a* and b* used above are used in connection with a recognized standard color space system. In the color space system, the colors are plotted in a plane of the CIELAB-system in which a' represents red and green and b* represents yellow and blue. The lightness of the color is on an axis at right angles to the plane going from black or L* = 0 to white where L* = 100. Thus the color would be grey in the center of the plane with the chroma increasing from the center toward the outer perimeter of the plane. The extreme edge of the plane defines the highest chroma. For example, a red light emitting laser would have high chroma. Between the center and edge, there are various gradations of the red as for example, a pink. Thus, there are planes of these colors which move up and down the L* axis or the lightness value axis. For every illuminant-observer combination of the tristimulus value, the color coordinates can be readily calculated and also can be measured. It is well known to those skilled in the art of color, that any pigment or any color can have a different appearance depending upon the illuminant. For example a color under fluorescent light may be quite different from the color under sunlight or under a tungsten lamp. In accordance with the present invention, it is important that the matched colors of the pigments 21 and 22 at a certain angle be compared under the same illuminant. Thus a pigment may be irradiated with a predetermined amount of energy across the wavelength to provide a graph of power versus wavelength. The quantity of light or energy impinging or striking the pigment at a given wavelength will influence the reflectance curve. The spectral power distribution from the light source is integrated with the eye response function typically designated as \bar{x} , \bar{y} and \bar{z} and the reflectance spectrum to yield the tristimulus values X, Y and Z.

[0015] In connection with the present invention, the L*, a*, b* (CIELAB) color space is used to describe the invention since this system is the most uniform (linear in color) known to date and is generally accepted worldwide for practical use. Thus, in the CIELAB color space, the color of any optically variable device can be characterized by the three tristimulus values, X, Y and Z. These tristimulus values take into account the spectral distribution of the light source, the reflectance of the optically variable pigment and the spectral sensitivity to the human eye. It is from these X, Y and Z values that the L*, a*, b* coordinates are calculated as are the related values of L* (lightness), C* (chroma), h (hue) and associated color differences i.e. delta L*, delta C* and delta h. The appropriate color formulae are listed below.

$$L^* = 116 (Y/Y_n)^{1/3} - 16 \quad \text{Formula 1}$$

$$a^* = 500 [(X/X_n)^{1/3} - (Y/Y_n)^{1/3}] \quad \text{Formula 2}$$

$$b^* = 200 [(Y/Y_n)^{1/3} - (Z/Z_n)^{1/3}] \quad \text{Formula 3}$$

$$C^* = (a^{*2} + b^{*2})^{1/2} \quad \text{Formula 4}$$

$$h = \arctan (b^*/a^*) \quad \text{Formula 5}$$

Where X_n , Y_n , or Z_n are tristimulus values for an ideal white diffuser and the illuminant-observer combination.

[0016] The designs for the paired optically variable pigments are selected so that in the $a^* b^*$ diagrams of the same there are crossover points at which the optically variable pigments will have the same hue and chroma. The manner in which these colors of the optically variable pigments change with angle is dependent upon the ambient lighting conditions. Thus in connection with the present invention, three different types of illumination are considered. Illuminant A represents illumination from an incandescent (tungsten) light at a temperature of 2856° Kelvin. Illuminant C represents average sunlight with a correlated color temperature of 6770° Kelvin and Illuminant F represents light from a cool white fluorescent source at a correlated color temperature of 4200° Kelvin. These three illuminants have been chosen because they represent the most common forms of illumination for both interior and exterior lighting conditions.

[0017] In Tables I to VI below and in the drawings in Figures 3-6 there are shown representative samples of designs which are possible under illuminant A. Thus for example in Table I, there are shown ten examples of paired optically variable pigments. Selecting Example 1 in Table I, Design 1 has a thin film interference stack of two quarter waves at the 620 nanometers and for Design 2 four quarter waves at 587 nanometers. For Design 1 and Design 2 in this example, the color is almost the same at 10° viewing orientation.

TABLE I

PAIRED OPTICALLY VARIABLE PIGMENTS ILLUMINANT A AT 10°

[0018] Table II set forth below shows the calculated color values of L^* , a^* , b^* , h and C^* for each pair in the Example 1-10 consisting of Design 1 and Design 2. Example 1 at 10°, of the pair of optical variable pigments has an L^* value of 77.85 and Design 2 has an L^* value of 79.76. With the angle shifted to 45°, Design 1 has an L^* value of 91.89 and Design 2 has an L^* value of 76.77. In addition, Table II shows the calculated color parameters for the designs shown in Table I.

	b,	45 deg.	77.49	36.42	46.37	51.85	58.96	

[0019] The color difference at 10° viewing angle as well as that for a 45° viewing angle for each example is set forth below in Table III. The total color difference delta E (ΔE) between the colors of the paired optically variable pigments are calculated from L*, a*, and b* using Formula 6:

$$\Delta E^* = [(\Delta L^*)^2 + (\Delta a^*)^2 + (\Delta b^*)^2]^{1/2}$$

Formula 6

TABLE III (continued)

TOTAL COLOR DIFFERENCE (DELTA E) FOR EXAMPLES IN TABLE I		
Pair Total Color Difference (Delta E)		
Des. Pair Example	10 Deg.	45 Deg.
10	11.52	18.50
Design pairs are from the 10 degree designs. Note: The 45° data shows the color difference at 45° for the 10 degree color pairs.		

[0020] Thus the lower the ΔE value, the closer the colors match. ΔE includes not only hue and color saturation but the brightness of the paired optically variable pigments as well.

[0021] Figures 3 and 4 of the drawings are graphical representations of what has been presented in Tables I, II, and III. Figure 3 shows how closely the colors are matched in hue and chroma for the examples of the paired designs of the paired optically variable pigments in the a^*b^* color space. From Figure 3 it can be seen that the pairs are of almost identical colors at the 10° orientation. However, when the pairs are tilted to 45° the two designs of each color pair and each of the examples have widely different color properties which is what is desired in accordance with the present invention. Thus there have been provided ten examples of paired optically variable pigments. Each have essentially no hue and chroma difference at 10° but at 45° have widely divergent hue and chroma contrasts. In the graphs in Figure 3 and 4, the paired designs are identified in accordance with Tables I, II and III. Thus Example 1 with design 1 is labeled "1-1" and Example 1 with design 2 is labeled "1-2".

[0022] In Tables IV, V and VI below there are set forth eight examples of paired designs for paired optically variable pigments in accordance with the present invention in which the converse of that obtained in the ten examples in Tables I, II and III has been given in which color differences are minimized at 45° and color changes occur at a shifted angle, as for example at 10°.

TABLE IV

PAIRED OPTICALLY VARIABLE PIGMENTS ILLUMINANT "A" AT 45°

6	71.56	10.33
7	20.67	20.31
8	102.89	9.75
Design pairs are from the 45 degree designs. Note: The 10° data shows color difference for the 45 degree pairs at 10°.		

EP 0 914 261 B1

[0023] Graphical representations of the data shown in Tables IV, V and VI are shown in Figures 5 and 6 of the drawings in which Figure 5 shows the color divergence at the 10° with illuminant A and Figure 6 shows no color divergence at an angle of 45° with illuminant A.

[0024] Tables VII, VIII and IX below have the same data as Tables I, II and III except for illuminant C and with Figures 7 and 8 giving graphical representations showing the matching of colors at 10° and a divergence of the colors at 45°.

10	12.60	22.51
Design pairs are from the 10° designs.		
Note: The 45° data shows color difference at 45° for the 10° color pairs.		

[0025] In Tables X, XI and XII there are shown the designs corresponding to the designs shown in Tables IV, V and VI under illuminant C rather than illuminant A. Figures 9 and 10 represent graphically the information set forth in Tables X through XII and show the divergence in colors at 10° and the matching of colors at 45°.

8	127.72	7.27
Design pairs are from the 45° designs.		
Note: The 10° data shows color difference at 10° for the 45° color pairs.		

[0028] In viewing the data set forth in the foregoing tables, it can be seen that there is a color difference for different types of illumination. In other words, under one illuminant there may be an exact color match whereas under another illuminant there may no longer be an exact color match. Thus there is a color change which traditionally is known as

EP 0 914 261 B1

color metamerism. In viewing Table III, example 1 gives the lowest color difference of 1.92 whereas example 6 gives the highest color difference of 29.63 for designs for matching colors at 10°. Table VI for matching colors at 45°, the minimum color difference is 2.52 for example 1 and the maximum color difference is 27.77 for example 5. Similar analyses can be carried out for Tables IX, XII, XV and XVIII, to give a minimum of 4.49 and a maximum 30.21 for Table IX, a minimum of 4.66 and a maximum 28.2 for Table XII, a minimum 0.95 and a maximum of 37.4 for Table XV and a minimum of 0.53 and a maximum of 32.8 for Table XVIII.

[0029] Similarly, the data in Tables I through XVIII can be analyzed to ascertain the paired designs under the illuminants A, C and F as set forth below in Table XIX.

TABLE XIX

TOTAL COLOR DIFFERENCE FOR PAIRED OPTICALLY VARIABLE PIGMENTS FROM DIELECTRIC THICKNESS TRACKS UNDER ILLUMINANTS "A", "C" AND "F"					
Pair	Ill.	Angle	Delta E	Designs 1 and 2	
1	A	10	1.92	2 qw @ 620 & 4 qw @ 587	
3	A	10	5.55	3 qw @ 697 & 5 qw @ 649	
1	A	45	2.52	3 qw @ 480 & 4 qw @ 679	
3	A	45	5.26	4 qw @ 604 & 6 qw @ 625	
1	C	10	4.49	2 qw @ 625 & 4 qw @ 582	
3	C	10	6.29	3 qw @ 692 & 5 qw @ 641	
7	C	45	4.66	2 qw @ 395 & 5 qw @ 646	
2	C	45	6.99	4 qw @ 600 & 6 qw @ 617	
7	F	10	0.95	3 qw @ 647 & 6 qw @ 704	
9	F	10	2.07	4 qw @ 620 & 6 qw @ 605	
7	F	45	0.53	2 qw @ 394 & 5 qw @ 648	
4	F	45	2.38	5 qw @ 573 & 6 qw @ 698	

[0030] As can be seen in Table XIX above, the best two design pairs for each illuminant and at each angle have been selected. For example, two design pairs at a 10° viewing angle under Illuminant A were shown to have the lowest color mismatch. Similarly, two different paired designs had the best color match at a 45° viewing angle under Illuminant A. Those which have been selected are the ones which have the smallest color difference for the chosen angle. Similarly, the examples have been selected for the best two color matched pairs under Illuminant C and similarly for Illuminant F under the two different orientations. Using this criteria the best overall design pair was found under Illuminant F at 45°. By reviewing Table XIX, the color difference for the pair: 2 qw at 394 nanometers and 5 qw at 648 nanometers has a ΔE at 0.53.

[0031] In Table XX set forth below, the two design pairs selected in Table XIX were analyzed to ascertain whether or not a color match still existed under different illuminants. when those designs are forced under Illuminant A, the color difference in terms of ΔE is now 36.44 and when it is placed under Illuminant C it has a value of only 6.15. Thus it can be seen that when the best pair of optically variable pigments under Illuminant F is placed under a different

EP 0 914 261 B1

illumination the color match is no longer an exact color match. Other paired designs were also viewed under different illuminants to see the effect in their ΔE color difference and this data has been tabulated in Table XX.

[0032] In the event that the present invention is utilized for preparing optically variable pigments to be used with

currency to prevent counterfeiting, it should be appreciated that bank-note exchange is most likely to take place under cool fluorescent lighting as typically found in banks and retail stores. It is therefore believed that design pairs should be utilized which have matching colors under such lighting as for example Illuminant F as set forth above. Utilizing such principles the best overall design pair would be one involving two quarter waves at 394 nanometers and five quarter waves at 648 nanometers.

[0033] Although the design pair involving two quarterwaves at 394 nanometers and five quarterwaves at 648 nanometers is the best overall design pair, the design at 394 nanometers does not have much of an optical shift, as can be seen by referring to Figures 13 and 14. This design pair, labeled "7-1" and "7-2" does have a divergence of color at 10°, but the change in color for the two quarterwave design is small. Thus, a preferable design pair would be Pair 4, which has the designs five quarterwaves at 573 nanometers and six quarterwaves at 698 nm. Both of these designs have substantial color shift with angle. They are widely separated in color at 10° and have a fairly good color match at 45°.

[0034] It can be seen by referring to Tables II, V, VIII, XI, XIV and XVII that the color match in terms of hue is, for all practical purposes, an exact match. The ΔE differences for the various design pairs as shown in Tables III, VI, IX, XII, XV and XVIII are a consequence of slight variations of brightness, L^* and in chroma, C^* . These color variations can be minimized by adding a black or neutral transparent pigment or nontransparent pigment to the design of the pair which has the highest chroma and brightness value. The addition is made until the brightness and chroma are matched to the lower chroma and brightness design of the pair. Thus, all design pairs can be optimized for color matching by the judicious additions of other color modifying materials.

[0035] All the foregoing principles can be utilized in conjunction with the optically variable device 11 shown in Figure 1 in which paired optically variable pigments utilizing those principles can be incorporated into the two different optical variable devices 17 and 18 shown therein and which can be utilized in the form of an ink or a paint with the appropriate vehicles for the pigments.

[0036] To achieve high color saturation and to have large color travel as a function of viewing angle which is desired in connection with the present invention, interference type pigments are utilized. In such pigments, metal dielectric or all dielectric interference stacks are utilized.

[0037] A typical metal dielectric asymmetric interference stack 31 as shown in Figure 15 is formed as a sheet on a soluble release layer 32 deposited on a flexible web 33 serving as a substrate. The multilayer interference thin film stack 31 can be removed by passing the web or substrate through a solvent bath. As the soluble release layer 32 dissolves, the thin sheet of interference film 31 disintegrates into a multitude of flakes. Since the flakes have two planar surfaces, it is desirable to provide an optical design for the multilayer interference stack or film so that it is symmetric and presents the same design on each side. After collecting the flakes and washing them to free them of release material, a pigment is produced by grinding the flakes to a size ranging from 2 to 200 microns and preferably a size ranging from 2 to 20 microns by grinding or pulverizing without destroying the color characteristics of the flakes. The flakes should have an aspect ratio of at least 2 to 1 with respect to the surfaces of the flakes and the thicknesses of the flakes and preferably 10 to 1 in order to preserve the correct particle orientation when they are placed in the desired vehicle for an ink or a paint to maximize the brightness and color purity of the ink or paint.

[0038] Thus in accordance with the present invention it is desirable to utilize a symmetric metal dielectric stack 31 as shown in Figure 15 which can be comprised of only three materials and five layers to produce a strongly dichroic optically variable opaque pigment. It is comprised of a semi-opaque metal layer 36 which is formed on the release coat 32 carried by the flexible web 33. The layer 36 is followed by a dielectric layer 37, a thick metal reflecting layer 38, another dielectric layer 39 and a final thin semi-opaque metal layer 41. For the production of a hot stamping dichroic foil (i.e., an optically variable foil), only three layers are required. These three layers would consist of: 36, 37 and 38, as shown in Figure 15. In this form, the layers 36 and 38 are inverted. When the multilayer thin film is separated from the release coat 32 and the flexible web 33 and attached by means of an adhesive to a counter surface, the layer 36 faces the viewer. By way of example each of the thin metal layers 36 and 41 may be formed of a nominal five nanometer thick layer of chromium and each of the dielectric layers 37 and 39 can be formed from a suitable dielectric material such as silicon dioxide to an optical thickness of a plurality of half waves at a particular design wavelength. The metal reflecting layer 38 may be formed of a layer of aluminum formed to the thickness of approximately 80 nanometers to provide opacity and high reflection. Although a layer of reflecting metal of greater thickness can be utilized, it is believed that it is preferable to minimize the stress in this layer by providing a thin layer as well as to maintain the correct aspect ratio for the product when in the form of a pigment.

[0039] It should be appreciated that the materials mentioned are by way of example only and that other grey metals such as nickel and Inconel when n and k (n =real part of refractive index and k =imaginary part of the refractive index) have a high nk product can be utilized in place of chromium. Also in place of silicon dioxide having an index of refraction of 1.46 for the dielectric, other low index materials having an index of refraction of 1.65 or less such as magnesium fluoride having an index of 1.38 and aluminum oxide having an index of 1.65 can be utilized or even lower reflecting metals, such as chromium, nickel or palladium for example, can be used for lower reflecting pigments. In place of

aluminum as the metal reflecting layer, the optical metals such as gold, copper and silver can be utilized.

[0040] It also should be appreciated if desired, an asymmetric metal dielectric interference stack can be provided if that is desired. When such is the case, the metal reflecting layer 37 can be formed directly onto the release layer followed by the dielectric layer 39 and the thin metal semitransparent metal layer 41. It must be appreciated that such a three-layer design when removed from the web would produce an optically variable pigment with lower chroma than a five-layer symmetrical stack but would nevertheless have dichroic features, i.e., color shift with viewing angle, and could potentially be used to produce lower chroma pairs of pigments with a color match at one angle and no color match at any other angle. These pigments would be equivalent to those already described, except that they would have lower overall chroma so that the designs listed in Tables I, IV, VII, X, XIII and XVI would have chroma compression around the origin of the a^*b^* plot, but nevertheless would have essentially the same color hue match.

[0041] If desired an all dielectric interference stack can be provided where that is deemed appropriate where the additional layers typically required can be provided without undue expense. As is shown in Figure 16, an all dielectric interference stack 51 can be provided on a release coat 52 carried by a flexible web or substrate 53. Such a dielectric stack is comprised of alternate layers 54 and 56 with the low index layers being identified as L1 through L5 and having an index refraction of 1.35 to 1.65 and the high index layers being identified as H1 through H4 having a high index of refraction of 1.7 to 2.4 for a total of nine layers. A wide variety of low and high index materials can be utilized in such a multilayer stack. For example, zinc sulfide can be utilized with magnesium fluoride and titanium dioxide can be utilized with silicon dioxide. Other dielectric materials can also be used such as germanium, silicon, indium tin oxide, indium oxide and silicon monoxide.

[0042] The design of an all dielectric stack may be expressed as follows:

$$(L/2 H L/2)^n$$

where L and H designate quarter wave optical thickness of the low and high index layers respectively such that L/2 represents an eighth wave optical thickness of the low index layer where $n \geq 2$. Such a multilayer stack can be separated from the web 53 in the same manner hereinbefore described and reduced to the sizes hereinbefore described to provide platelets with an aspect ratio in which the major planar dimension of the surfaces is at least two to one with respect to the thickness and preferably ten to one to maximize brightness and color purity of the ink or paint in which pigment platelets or flakes or particles are to be used. Again it should be appreciated, that if desired an asymmetric all dielectric stack can be created merely by combining the first four layers L1 and L2 and H1 and H2.

[0043] For example, in connection with the foregoing it has been found that paired optically variable foils and/or pigments with the same matched colors at 0° and 45° for an all-dielectric design can be achieved in which chroma and hue match. One design consists of $(1 \text{ QW ZrO}_2 / 1 \text{ QW SiO}_2)^3 / 1 \text{ QW ZrO}_2$ and an additional design: $(1 \text{ QW ZrO}_2 / 3 \text{ QW SiO}_2)^3 1 \text{ QW ZrO}_2$ in which the thicknesses of the quarter wave ranged from 400 nanometers to 2500 nanometers. For the single quarter wave design there are three possible matched pairs at 0° two matched pairs at 45°. Conversely, analyzing chroma and hue variation for the design $(1 \text{ QW ZrO}_2 / 3 \text{ QW SiO}_2)^3 / 1 \text{ qw ZrO}_2$ at 0° there are two color match pairs at 45° and there are four color match pairs achievable. Table XXI shows the dielectric pairs that have a color match at 0° or at 45°.

[0044] In connection with the foregoing, it should be appreciated that merely increasing the number of pairs of the dielectric design does not make it possible to achieve the coincidence of color matching. However, by increasing the individual thicknesses of the layers, coincidence in color matching can be achieved.

TABLE XXI

Dielectric Pairs That Match Hue and Chroma at Angle					
Design	Angle	Design Pair	a*	b*	L*
$(\text{ZrO}_2/\text{SiO}_2)^3\text{ZrO}_2$	0 Deg.	1 qw @ 495nm	-43.8	-6.41	83.61
		1 qw @ 1480nm	-45.25	-5.56	57.96
		1 qw @ 540nm	-33.6	50.83	90.95
		1 qw @ 1680nm	33.75	54.24	75.20
$(\text{ZrO}_2/\text{SiO}_2)^3\text{ZrO}_2$	45 Deg.	1 qw @ 610nm	-26.63	57.32	88.97
		1 qw @ 1860nm	-26.7	55.05	73.70
		1 qw @ 550nm	-37.45	-1.47	83.25
		1 qw @ 1630nm	-39.42	-1.2	59.28

TABLE XXI (continued)

Dielectric Pairs That Match Hue and Chroma at Angle					
Design	Angle	Design Pair	a*	b*	L*
(ZrO ₂ /3 SiO ₂) ³ ZrO ₂	0 Deg.	1 qw @ 590nm	16.18	44.19	78.33
		1 qw @ 870 nm	18.2	42.68	61.57
		1 qw @ 615nm	43.49	17.89	70.62
		1 qw @ 940nm	44.46	16.09	46.57
(ZrO ₂ /3 SiO ₂) ³ ZrO ₂	45 Deg.	1 qw @ 700nm	45.13	9.82	67.18
		1 qw @ 1030nm	45.68	7.98	48.90
	-	1 qw @ 760nm	30.4	-20.84	55.39
		1 qw @ 2220nm	31.32	-19.38	51.52

[0045] Thus it can be seen that metal-dielectric as well as all dielectric interference thin films can be utilized in the optically variable pigments utilized herein to provide the paired optically variable pigments hereinbefore described.

[0046] The optically variable pigments of the present invention are inherently light fast. This inherency is derived from the fact that the color that emanates from the pigment is due to an interference effect and is not based on any chromophore that can be bleached by ultraviolet light. All the materials used in the construction of the optically variable pigment do not have any color or any chromophore and are, in fact, colorless in themselves. For example, the metals aluminum and chromium are silver and grey and the dielectric magnesium fluoride is water-white transparent.

[0047] In Figure 17, there is shown a pair of paired optically variable devices incorporating the present invention. On the left-hand side of Figure 17 there is shown a first or one paired optically variable device 71 and on the right-hand side there is shown a second or another paired optically variable device 72 with both devices 71 and 72 having the same color at one viewing angle. Thus device 71 has a centrally disposed first or inner optically variable device 76 in the form of a circle seated within a circular hole 77 provided in the second or outer optically variable device 78 in the form of a square or rectangle. Similarly, the second paired optically variable device 72 consists of an inner or first optically variable device 81 in the form of a circle which is disposed within a hole 82 provided in a second or outer variable device 83 in the form of a rectangle or square. The two devices 71 and 72 lie generally in the same plane and are disposed side by side in relatively close proximity to each other. The device 76 in the form of the circle in device 71 and the device 83 in the form of a rectangle carry the same optically variable pigment and similarly, the device 78 and the device 81 of the device 71 and the device 72 respectively carry the same optically variable pigment.

[0048] Thus by way of example as shown below, the pigment carried by the devices 76 and 83 can carry a pigment which shifts from green to magenta and devices 78 and 81 can carry a pigment which shifts from green to blue. When the devices 71 and 72 are at one angle both devices 71 and 72 can have the same color of green whereas when the devices 71 and 72 are shifted at an angle, the devices will have two colors, magenta and blue with device 71 having a magenta center and a blue border and conversely the device 72 will have a blue center and a magenta border.

[0049] In connection with the optically variable devices, it is possible to take batches of the optically variable pigments which may vary slightly in hue and blend the same to achieve the same color specification in production quantities. Also, color additive theory makes it possible to provide a multitude of additional colors if desired.

[0050] Also in accordance with the present invention in the event there is color metamerism at a certain color under a desired illuminant and if is desired to achieve an exact color match, this can be achieved by adding color used subtractively or additively to achieve an exact color.

[0051] In Figures 18, 19 and 20 there is disclosed another embodiment of a paired optically variable device 91 utilizing paired optically variable pigments incorporating the present invention. The optically variable device 91 is mounted on a substrate 92 of the type hereinbefore described having a surface 93. An optically variable device 94 has an optically variable pigment in the form of flakes 96 disposed in a solidified clear vehicle 97 on the surface 93. Another optically variable device 98 which utilizes an optically variable pigment 99 is disposed in a clear solidified toner vehicle 101 on surface 102 and provides a symbol or message which for example can be in the form of a logo 106. The symbol or logo 106 disappears at one angle of incidence with the optically variable pigments 96 and 99 having the same color as for example green so that the symbol is masked at normal incidence but appears when the device is tilted to a different angle to cause color shifts to occur as for example a color shift from green to blue with one pigment and green to magenta with the other pigment. Thus by way of example there could appear a green square at normal incidence and at an angle, the symbol 106 would appear in blue on a magenta background as depicted in Figure 19.

[0052] The optically variable device 91 can be manufactured in a number of ways. For example the optically variable

pigment 96 which in this example could be a green to magenta optically variable pigment 96 would be placed in the solidified liquid vehicle 97 on the surface 93. The symbol or logo 106 is then formed on the surface of the solidified liquid vehicle 97 by various means. It can be either printed onto the surface 102 or it can be imaged using a toner by means of electrophotography. In case of the electrophotographic process, a toner that may be clear or black can be provided in the form of an image or symbol. Once the toner image has been formed on the surface 102, the image is then dusted with the other optically variable pigment 99 of the pair. This dusting is known as a "bronzing technique". In accordance with the description above, the optically variable pigment 99 can be a green-to-blue shifter. In order to fuse the optically variable pigment 99 to the toner vehicle image, the device is overlaid with a layer of flexible sheeting and passed through a heated laminator. This causes the toner to melt and to allow the overlying pigment 99 to become embedded in the toner vehicle 101. During the process of melting, the planar platelets align themselves parallel to the surface of the device, i.e., the surface 93. After passing through the laminator, the flexible sheeting is removed from the solidified toner image. No sticking of the toner to the flexible sheet occurs because pigment is between the toner and the flexible sheet. Alternatively, the logo 106 could be printed using gravure, silk screen, intaglio or other printing methods.

[0053] Another embodiment of a paired optically variable device is shown in Figures 21, 22 and 23 in which the paired optical device 111 is provided on a substrate 112 which can be of a suitable type. It can be flexible or rigid and can be formed of cloth, paper, plastic and the like. The substrate 112 is provided with an upper surface 113 which has first and second optically variable devices 116 and 117 disposed thereon. The devices 116 and 117 are in the form of optically variable foils 118. The optically variable devices 116 and 117 are placed upon the surface 113 of the substrate 112 by first and second hot stamps (not shown) which are in registration into a dot matrix. As in the previous embodiments of the invention, the foils utilized in the devices 116 and 117 are of substantially the same color at the same angle of incidence and are of different colors at all other angles of incidence. Thus, as in the previous embodiments, one of the foils could shift from green-to-blue and the other one could shift from green-to-magenta so that at one angle, the optically variable foil in the devices 116 and 117 have the same color as for example green and at another angle the optically variable thin layer coatings in the devices 116 and 117 have two different colors, blue and magenta. In the dot matrix shown in Figures 21 and 22, the dots 116 utilized in the device 111 can be of a green-to-blue shifter whereas the dots 117 can be the green-to-magenta shifter. These foils can be made either by placing optically variable pigment flakes into a hot stamp polymer film carried by a release coat on a flexible substrate or by placing multilayer optically variable thin film coatings serving as optically variable specular foils carried by a release coat on a flexible substrate. Thus in the hot stamp matrix transfer shown in Figure 21 at one angle, all of the dots have the same color whereas in Figure 22 at a different angle, the pattern of the dots which make up the numeral 20 are formed of the green to magenta shifter so that when the angle of incidence is changed for the paired optically variable device 111 the dots on the substrate 112 will change from an all green color to a blue color for the background and to a magenta for the numeral 20 to provide a good contrast so that the numeral 20 can be readily seen by the human eye. With such an arrangement it can be seen that symbols, numerals and other devices such as a logos can be incorporated into the optically variable devices to aid in identification and also to provide anti-counterfeiting capabilities.

[0054] Although the embodiment shown in Figures 21, 22 and 23 has been disclosed as being a hot stamp transfer device, it should be appreciated that the same principles can be utilized in conjunction with a paint or an ink incorporating the optically variable pigments of the present invention.

[0055] From the foregoing, it can be seen that the paired optically variable devices of the present invention all utilize the same principal of having two interference designs having optically variable properties and that the paired optically variable designs have the same color at one angle of incidence and at all other angles have non-matching colors. Thus, in the case of pigments, it can be seen that even though it is difficult to even replicate one of the pigments with its color shift, to provide a pair of pigments in which the pair of pigments have the same matching color at the same angle would be much more difficult to replicate. Therefore the use of paired optically variable pigments contained in a printed image would make counterfeiting very difficult if not impossible. In accordance with the present invention it should be appreciated that these paired optically variable pigments can also be paired with another pair of optically variable pigments or paired with non-shifting pigment. Also, one interference optically variable pigment can be paired with a non-shifting pigment so that the non-shifting pigment matches the color of an optically variable pigment at a certain angle. Thus by example in Figures 21 and 22, the dot matrix can include a set of dots in registration having a pigment which is in the form of a non-shifting color which matches the color of a shifting pigment, as for example green, so that the composite would have an overall green color at one angle and at different angles there would be a number 20 in magenta against a green background.

[0056] In connection with the foregoing, it should be appreciated that the highest chroma and the greatest color change with angle has been found with the metal dielectric type designs rather than with an all dielectric designs having the same number of layers. This is because the metal dielectric designs involve selective color absorption in addition to interference. The pigments display high chroma and hue changes with viewing angle while maintaining high luminance. The gamut of colors available to suppress counterfeiting is markedly increased by the use of paired optically

variable devices in accordance with the present invention.

Claims

1. A paired optically variable article comprising a substrate (12) having a first surface (13), wherein first and second optical devices (17, 18) are carried by said first surface, at least one of the first and second optical devices being optically variable and forming a pair carried by the first surface of the substrate in spaced-apart positions on the first surface of the substrate to permit viewing at the same time by the human eye, **characterised in that** said first and second optical devices having the same matching colour at one angle of incidence between 0° and 90° for a colour match angle and being without colour match at all other angles of incidence, said at least one of the first and second optical devices being optically variable being comprised of an optically variable pigment which can be utilised in inks, paints and foils.
2. A paired optically variable article as claimed in claim 1, further **characterised in that** said at least one of the first and second optical devices includes a metal-dielectric interference stack (31).
3. A paired optically variable article as claimed in claim 1, further **characterised in that** said at least one of the first and second optical devices includes an all dielectric interference stack (31).
4. A paired optically variable article as claimed in claim 1, further **characterised in that** said colour match angle is a low angle of incidence between 0-10°.
5. A paired optically variable article as claimed in claim 1, further **characterised in that** said colour match angle is a high angle of incidence of 30° or more.
6. A paired optically variable article as claimed in claim 1, further **characterised in that** said at least one of said first and second optical devices is non-shifting.
7. A paired optically variable article as claimed in claim 1, further **characterised in that** said at least one of the first and second optical devices is opaque.
8. A paired optically variable article as claimed in claim 7, further **characterised in that** said at least one of the first and second opaque optical devices includes an opaque optically variable pigment.
9. A paired optically variable article as claimed in claim 7, further **characterised in that** said at least one of the first and second opaque optical devices includes an opaque optically variable foil.
10. A paired optically variable article as claimed in claim 7, further **characterised in that** said at least one of the first and second optical devices is disposed in an ink vehicle to provide an ink.
11. A paired optically variable article as claimed in claim 7, further **characterised in that** said at least one of the first and second optical devices is disposed in a paint vehicle to provide a paint.
12. A paired optically variable article as claimed in claim 1, further characterised as including a release coat disposed on the first surface of the substrate and a hot stamp polymer film disposed over the release coat and wherein the first and second optical devices are incorporated into the hot stamp polymer film to form a hot stamp foil.
13. A paired optically variable article as claimed in claim 1, further **characterised in that** each of said optically variable devices includes an optically variable pigment.
14. A paired optically variable article as claimed in claim 13, further **characterised in that** each of said optically variable pigments is opaque.
15. A paired optically variable article as claimed in claim 1, further **characterised in that** each of said first and second optical devices includes an optically variable foil.
16. A paired optically variable article as claimed in claim 1, further **characterised in that** said first and second optical

devices form a first pair (71) and further including a second pair (72) of optical devices, at least one of the first and second optical devices in the second pair being optically variable, said first and second optical devices of said second pair having the same matching colour at one angle of incidence between 0° and 90° for a colour match angle and being without colour match at all other angles of incidence.

17. A paired optically variable article as claimed in claim 16, further **characterised in that** said first and second optically variable pigments have the same matching colour with an illuminant at a temperature at 2856° Kelvin.
18. A paired optically variable article as claimed in claim 16, further **characterised in that** said first and second optically variable pigments have the same matching colour with an illuminant at 6770° Kelvin.
19. A paired optically variable article as claimed in claim 16, further **characterised in that** said first and second optically variable pigments have the same matching colour with an illuminant having a temperature of 4200° Kelvin.
20. A paired optically variable article as claimed in claim 1, further characterised as comprising a symbol formed by an arrangement of the first and second optical devices.
21. A paired optically variable article as claimed in claim 1, further **characterised in that** said first and second optical devices are optically variable and wherein the first optical device is a symbol and the second optical device is a background for the symbol.
22. A paired optically variable article as claimed in claim 1, further **characterised in that** said first and second optical devices are optically variable specular opaque foils.
23. A paired optically variable article as claimed in claim 1, further characterised as including a hot stamp polymer film having said first and second optical devices incorporated therein and disposed on the substrate.
24. A paired optically variable article as claimed in claim 1, further **characterised in that** the first and second optical devices are comprised of multilayer interference stacks free of a common layer.
25. A method for creating a coloured reflectance from a substrate (12), said substrate having a first surface (13) and first and second optical devices (17, 18) formed of layers carried by said first surface, at least one of said first and second optical devices being optically variable, said first and second optical devices (17, 18) forming a pair carried by the first surface of the substrate in spaced apart positions on the first surface of the substrate to permit viewing at the same time by the human eye, the method being characterised as comprising forming said at least one optically variable device so it has one colour at one angle of incidence that is the same colour at the same angle of incidence as the colour of the second optical device, illuminating the paired optical devices from a light source whereby the pair of optical devices reflect the same colour at said one angle of incidence between 0° and 90° and being without colour match at all other angles of incidence, said at least one of the first and second optically variable devices being comprised of an optically variable pigment which can be utilised in inks, paints and foils.
26. A method as claimed in claim 25, further **characterised in that** the pair is a first pair (71) and further characterised as including providing a second pair (72) of first and second optical devices on the first surface of the substrate in spaced apart positions without overlap with at least one of the first and second optical devices of the second pair being optionnally variable to permit viewing at the same time of the first and second pairs by the human eye when the first and second pairs are illuminated from the same light source the second pair reflects colour at said one angle which is the same as the colour reflected by the first pair at said one angle and is without said colour match at all other angles of incidence.
27. A method as claimed in claim 25, further characterised as including the step of arranging the first and second optical devices to provide a symbol which is invisible at said one angle of incidence and which is visible at other angles of incidence.

Patentansprüche

1. Paariger optisch variabler Gegenstand

- mit einem Substrat (12), das eine erste Oberfläche (13) hat,
- wobei erste und zweite optische Vorrichtungen (17, 18) von der ersten Oberfläche getragen werden,
- wobei wenigstens eine Vorrichtung der ersten und zweiten optischen Vorrichtungen optisch variabel ist und ein Paar bildet, das von der ersten Oberfläche des Substrats in beabstandeten Lagen auf der ersten Oberfläche des Substrats getragen wird, um ein gleichzeitiges Betrachten durch das menschliche Auge zu ermöglichen,

dadurch gekennzeichnet,

- **dass** die ersten und zweiten optischen Vorrichtungen die gleiche übereinstimmende Farbe bei einem Einfallswinkel zwischen 0° und 90° für einen Farbübereinstimmungswinkel und bei allen anderen Einfallswinkeln keine Farbübereinstimmung haben,
- wobei die wenigstens eine Vorrichtung der ersten und zweiten optischen Vorrichtungen, die optisch variabel ist, von einem optisch variablen Pigment gebildet wird, das in Tinten, Farben und Folien verwendet werden kann.

2. Paariger optisch variabler Gegenstand nach Anspruch 1, der weiterhin **dadurch gekennzeichnet ist, dass** die wenigstens eine Vorrichtung der ersten und zweiten optischen Vorrichtungen ein Metall-Dielektrum-Interferenzschichtsystem (31) aufweist.

3. Paariger optisch variabler Gegenstand nach Anspruch 1, welcher weiterhin **dadurch gekennzeichnet ist, dass** die wenigstens eine Vorrichtung der ersten und zweiten optischen Vorrichtungen ein insgesamt dielektrisches Interferenzschichtsystem (31) aufweist.

4. Paariger optisch variabler Gegenstand nach Anspruch 1, welcher weiterhin **dadurch gekennzeichnet ist, dass** der Farbübereinstimmungswinkel ein niedriger Einfallswinkel zwischen 0 bis 10° ist.

5. Paariger optisch variabler Gegenstand nach Anspruch 1, welcher weiterhin **dadurch gekennzeichnet ist, dass** der Farbübereinstimmungswinkel ein großer Einfallswinkel von 30° oder mehr ist.

6. Paariger optisch variabler Gegenstand nach Anspruch 1, welcher weiterhin **dadurch gekennzeichnet ist, dass** die wenigstens eine Vorrichtung der ersten und zweiten optischen Vorrichtungen nicht verschiebend ist.

7. Paariger optisch variabler Gegenstand nach Anspruch 1, welcher weiterhin **dadurch gekennzeichnet ist, dass** die wenigstens eine Vorrichtung der ersten und zweiten optischen Vorrichtungen opak ist.

8. Paariger optisch variabler Gegenstand nach Anspruch 7, welcher weiterhin **dadurch gekennzeichnet ist, dass** die wenigstens eine Vorrichtung der ersten und zweiten opaken optischen Vorrichtungen ein opakes optisch variables Pigment aufweist.

9. Paariger optisch variabler Gegenstand nach Anspruch 7, welcher weiterhin **dadurch gekennzeichnet ist, dass** die wenigstens eine Vorrichtung der ersten und zweiten opaken optischen Vorrichtungen eine opake optisch variable Folie aufweist.

10. Paariger optisch variabler Gegenstand nach Anspruch 7, welcher weiterhin **dadurch gekennzeichnet ist, dass** die wenigstens eine Vorrichtung der ersten und zweiten optischen Vorrichtungen in einem Tintenträger zur Bildung einer Tinte angeordnet ist.

11. Paariger optisch variabler Gegenstand nach Anspruch 7, welcher weiterhin **dadurch gekennzeichnet ist, dass** die wenigstens eine Vorrichtung der ersten und zweiten optischen Vorrichtungen in einem Farbträger zur Bildung einer Farbe angeordnet ist.

12. Paariger optisch variabler Gegenstand nach Anspruch 1, welcher weiterhin **dadurch gekennzeichnet ist, dass** er eine Trennmittelbeschichtung, die auf der ersten Oberfläche des Substrats angeordnet ist, und einen Heißprägepolymerfilm aufweist, der über der Trennmittelbeschichtung angeordnet ist, wobei die ersten und zweiten optischen Vorrichtungen in den Heißprägepolymerfilm zur Bildung einer Heißprägefolie eingeschlossen sind.

13. Paariger optisch variabler Gegenstand nach Anspruch 1, welcher weiterhin **dadurch gekennzeichnet ist, dass** jede der optisch variablen Vorrichtungen ein optisch variables Pigment aufweist.

14. Paariger optisch variabler Gegenstand nach Anspruch 13, welcher weiterhin **dadurch gekennzeichnet ist, dass** jedes der optisch variablen Pigmente opak ist.
- 5 15. Paariger optisch variabler Gegenstand nach Anspruch 1, welcher weiterhin **dadurch gekennzeichnet ist, dass** jede Vorrichtung der ersten und zweiten optischen Vorrichtungen eine optisch variable Folie aufweist.
- 10 16. Paariger optisch variabler Gegenstand nach Anspruch 1, welcher weiterhin **dadurch gekennzeichnet ist, dass** die ersten und zweiten optischen Vorrichtungen ein erstes Paar (71) bilden und ferner ein zweites Paar (72) von optischen Vorrichtungen aufweisen, wobei wenigstens eine Vorrichtung der ersten und zweiten Vorrichtungen in dem zweiten Paar optisch variabel ist, und wobei die ersten und zweiten optischen Vorrichtungen des zweiten Paares die gleiche übereinstimmende Farbe bei einem Einfallswinkel zwischen 0° und 90° für einen Farbübereinstimmungswinkel und keine Farbübereinstimmung bei allen anderen Einfallswinkeln haben.
- 15 17. Paariger optisch variabler Gegenstand nach Anspruch 16, welcher weiterhin **dadurch gekennzeichnet ist, dass** die ersten und zweiten optisch variablen Pigmente die gleiche übereinstimmende Farbe bei einer Lichtquelle mit einer Temperatur von 2856° Kelvin haben.
- 20 18. Paariger optisch variabler Gegenstand nach Anspruch 16, welcher weiterhin **dadurch gekennzeichnet ist, dass** die ersten und zweiten optisch variablen Pigmente die gleiche übereinstimmende Farbe bei einer Lichtquelle mit 6770° Kelvin haben.
- 25 19. Paariger optisch variabler Gegenstand nach Anspruch 16, welcher weiterhin **dadurch gekennzeichnet ist, dass** die ersten und zweiten optisch variablen Pigmente die gleiche übereinstimmende Farbe bei einer Lichtquelle mit einer Temperatur von 4200° Kelvin haben.
- 30 20. Paariger optischer variabler Gegenstand nach Anspruch 1, welcher weiterhin **dadurch gekennzeichnet ist, dass** er ein Symbol aufweist, dass von einer Anordnung der ersten und zweiten optischen Vorrichtungen gebildet wird.
- 35 21. Paariger optisch variabler Gegenstand nach Anspruch 1, welcher weiterhin **dadurch gekennzeichnet ist, dass** die ersten und zweiten optischen Vorrichtungen optisch variabel sind, wobei die erste optische Vorrichtung ein Symbol und die zweite optische Vorrichtung ein Hintergrund für das Symbol ist.
- 40 22. Paariger optisch variabler Gegenstand nach Anspruch 1, welcher weiterhin **dadurch gekennzeichnet ist, dass** die ersten und zweiten optischen Vorrichtungen optisch variable spiegelnde opake Folien sind.
- 45 23. Paariger optisch variabler Gegenstand nach Anspruch 1, welcher weiterhin **dadurch gekennzeichnet ist, dass** er einen Heißprägapolymerfilm aufweist, in den die ersten und zweiten optischen Vorrichtungen eingeschlossen sind und der auf dem Substrat angeordnet ist.
- 50 24. Paariger optisch variabler Gegenstand nach Anspruch 1, welcher weiterhin **dadurch gekennzeichnet ist, dass** die ersten und zweiten optischen Vorrichtungen aus mehrlagigen Interferenzschichtsystemen bestehen, die frei von einer gemeinsamen Schicht sind.
- 55 25. Verfahren zur Erzeugung einer farbigen Remission von einem Substrat (12), das eine erste Oberfläche (13) sowie erste und zweite optische Vorrichtungen (17, 18) hat, die von Schichten gebildet werden, die von der ersten Oberfläche getragen werden, wobei wenigstens eine Vorrichtung der ersten und zweiten optischen Vorrichtungen optisch variabel ist, die ersten und zweiten optischen Vorrichtungen (17, 18) ein Paar bilden, das von der ersten Oberfläche des Substrats in beabstandeten Lagen auf der ersten Oberfläche des Substrats getragen wird, um ein gleichzeitiges Betrachten durch das menschliche Auge zu ermöglichen, und das Verfahren **dadurch gekennzeichnet ist, dass** wenigstens eine optisch variable Vorrichtung so ausgebildet wird, dass sie eine Farbe bei einem Einfallswinkel hat, die die gleiche Farbe bei dem gleichen Einfallswinkel wie die Farbe der zweiten optischen Vorrichtung hat, dass die paarigen optischen Vorrichtungen von einer Lichtquelle beleuchtet werden, wodurch das Paar von optischen Vorrichtungen die gleiche Farbe bei dem einen Einfallswinkel zwischen 0° und 90° reflektiert und bei allen anderen Einfallswinkeln keine Farbübereinstimmung hat, und dass die wenigstens eine Vorrichtung der ersten und zweiten optisch variablen Vorrichtungen von einem optisch variablen Pigment gebildet wird, das in Tinten, Farben und Folien verwendet werden kann.
26. Verfahren nach Anspruch 25, welches weiterhin **dadurch gekennzeichnet ist, dass** das Paar ein erstes Paar

(71) ist, und ferner **dadurch gekennzeichnet ist, dass** es ein zweites Paar (72) von ersten und zweiten optischen Vorrichtungen auf der ersten Oberfläche des Substrats in beabstandeten Lagen ohne Überlappung aufweist, wobei wenigstens eine Vorrichtung der ersten und zweiten optischen Vorrichtungen des zweiten Paares optisch variabel ist, um das gleichzeitige Betrachten des ersten und zweiten Paares durch das menschliche Auge zu ermöglichen, wenn die ersten und zweiten Paare von der gleichen Lichtquelle beleuchtet werden, und wobei das zweite Paar eine Farbe bei dem einen Winkel reflektiert, die die gleiche ist wie die Farbe, die von dem ersten Paar bei dem einen Winkel reflektiert wird und bei allen anderen Einfallswinkeln keine Farbübereinstimmung hat.

27. Verfahren nach Anspruch 25, welches weiterhin **dadurch gekennzeichnet ist, dass** es den Schritt einschließt, die ersten und zweiten optischen Vorrichtungen so anzuordnen, dass sie ein Symbol bilden, das bei dem einen Einfallswinkel unsichtbar und bei den anderen Einfallswinkeln sichtbar ist.

Revendications

1. Article double optiquement variable comportant un substrat (12) ayant une première surface (13), dans lequel des premier et second dispositifs optiques (17, 18) sont portés par ladite première surface, au moins l'un des premier et second dispositifs optiques étant optiquement variable et formant une paire portée par la première surface du substrat dans des positions espacées sur la première surface du substrat pour permettre une observation dans le même temps par l'oeil humain, **caractérisé en ce que** lesdits premier et second dispositifs optiques ont la même couleur d'adaptation sous un angle d'incidence compris entre 0° et 90° pour l'angle d'adaptation de couleur et sont sans adaptation de couleur à tous les autres angles d'incidence, ledit, au moins un, des premier et second dispositifs optiques optiquement variables étant constitué d'un pigment optiquement variable qui peut être utilisé dans des encres, des peintures et des feuil.
2. Article double optiquement variable selon la revendication 1, **caractérisé en outre en ce que** ledit, au moins un, des premier et second dispositifs optiques comprend un empilage à interférence métal-diélectrique (31).
3. Article double optiquement variable selon la revendication 1, **caractérisé en outre en ce que** ledit, au moins un, des premier et second dispositifs optiques comprend un empilage à interférence entièrement diélectrique (31).
4. Article double optiquement variable selon la revendication 1, **caractérisé en outre en ce que** ledit angle d'adaptation de couleur est un petit angle d'incidence compris entre 0 et 10°.
5. Article double optiquement variable selon la revendication 1, **caractérisé en outre en ce que** ledit angle d'adaptation de couleur est un grand angle d'incidence de 30° ou plus.
6. Article double optiquement variable selon la revendication 1, **caractérisé en outre en ce que** ledit, au moins un, desdits premier et second dispositifs optiques n'est pas mobile.
7. Article double optiquement variable selon la revendication 1, **caractérisé en outre en ce que** ledit, au moins un, des premier et second dispositifs optiques est opaque.
8. Article double optiquement variable selon la revendication 7, **caractérisé en outre en ce que** ledit, au moins un, des premier et second dispositifs optiques opaques comprend un pigment opaque optiquement variable.
9. Article double optiquement variable selon la revendication 7, **caractérisé en outre en ce que** ledit, au moins un, des premier et second dispositifs optiques opaques comprend un feuillet opaque optiquement variable.
10. Article double optiquement variable selon la revendication 7, **caractérisé en outre en ce que** ledit, au moins un, des premier et second dispositifs optiques est disposé dans un véhicule d'encre pour constituer une encre.
11. Article double optiquement variable selon la revendication 7, **caractérisé en outre en ce que** ledit, au moins un, des premier et second dispositifs optiques est disposé dans un véhicule de peinture pour constituer une peinture.
12. Article double optiquement variable selon la revendication 1, **caractérisé en outre en ce qu'il** comprend un revêtement anti-adhérent disposé sur la première surface du substrat et un film de polymère estampé à chaud disposé sur le revêtement anti-adhérent, et dans lequel les premier et second dispositifs optiques sont incorporés

dans le film de polymère estampé à chaud pour former un feuil estampé à chaud.

13. Article double optiquement variable selon la revendication 1, **caractérisé en outre en ce que** chacun desdits dispositifs optiquement variables comprend un pigment optiquement variable.

14. Article double optiquement variable selon la revendication 13, **caractérisé en outre en ce que** chacun desdits pigments optiquement variables est opaque.

15. Article double optiquement variable selon la revendication 1, **caractérisé en outre en ce que** chacun desdits premier et second dispositifs optiques comprend un feuil optiquement variable.

16. Article double optiquement variable selon la revendication 1, **caractérisé en outre en ce que** lesdits premier et second dispositifs optiques forment une première paire (71) et comprenant en outre une seconde paire (72) de dispositifs optiques, au moins l'un des premier et second dispositifs optiques de la seconde paire étant optiquement variable, lesdits premier et second dispositifs optiques de ladite seconde paire ayant la même couleur d'adaptation sous un angle d'incidence compris entre 0° et 90° pour un angle d'adaptation de couleur et étant sans adaptation de couleur à tous les autres angles d'incidence.

17. Article double optiquement variable selon la revendication 16, **caractérisé en outre en ce que** lesdits premier et second pigments optiquement variables ont la même couleur d'adaptation avec un illuminant à une température de 2856° Kelvin.

18. Article double optiquement variable selon la revendication 16, **caractérisé en outre en ce que** lesdits premier et second pigments optiquement variables ont la même couleur d'adaptation avec un illuminant à 6770° Kelvin.

19. Article double optiquement variable selon la revendication 16, **caractérisé en outre en ce que** lesdits premier et second pigments optiquement variables ont la même couleur d'adaptation avec un illuminant ayant une température de 4200° Kelvin.

20. Article double optiquement variable selon la revendication 1, **caractérisé en outre en ce qu'il** comporte un symbole formé par un agencement des premier et second dispositifs optiques.

21. Article double optiquement variable selon la revendication 1, **caractérisé en outre en ce que** lesdits premier et second dispositifs optiques sont optiquement variables, et dans lequel le premier dispositif optique est un symbole et le second dispositif optique est un fond pour le symbole.

22. Article double optiquement variable selon la revendication 1, **caractérisé en outre en ce que** lesdits premier et second dispositifs optiques sont des feuil opaques spéculaires optiquement variables.

23. Article double optiquement variable selon la revendication 1, **caractérisé en outre en ce qu'il** comprend un film de polymère estampé à chaud dans lequel sont incorporés lesdits premier et second dispositifs optiques et qui est disposé sur le substrat.

24. Article double optiquement variable selon la revendication 1, **caractérisé en outre en ce que** les premier et second dispositifs optiques sont constitués d'empilages d'interférence multicouches sans couche commune.

25. Procédé pour créer une réflectance colorée à partir d'un substrat (12), ledit substrat ayant une première surface (13) et des premier et second dispositifs optiques (17, 18) formés de couches portées par ladite première surface, au moins l'un desdits premier et second dispositifs optiques étant optiquement variable, lesdits premier et second dispositifs optiques (17, 18) formant une paire portée par la première surface du substrat en des positions espacées sur la première surface du substrat afin de permettre une observation dans le même temps par l'oeil humain, le procédé étant **caractérisé en ce qu'il** comprend la formation d'au moins un dispositif optiquement variable afin qu'il présente une couleur sous un angle d'incidence qui est la même couleur sous le même angle d'incidence que la couleur du second dispositif optique, à illuminer les dispositifs optiques doubles à partir d'une source de lumière de façon que la paire de dispositifs optiques réfléchissent la même couleur sous ledit angle d'incidence compris entre 0° et 90° et soient sans adaptation de couleur à tous les autres angles d'incidence, ledit, au moins un, des premier et second dispositifs optiquement variables étant constitué d'un pigment optiquement variable qui peut être utilisé dans des encres, des peintures et des feuil.

26. Procédé selon la revendication 25, **caractérisé en outre en ce que** la paire est une première paire (71) et **caractérisé en outre en ce qu'il** comprend la présence d'une seconde paire (72) de premier et second dispositifs optiques sur la première surface du substrat dans des positions espacées sans chevauchement, au moins l'un des premier et second dispositifs optiques de la seconde paire étant optiquement variable pour permettre une observation au même moment des première et seconde paires par l'oeil humain lorsque les première et seconde paires sont illuminées depuis la même source de lumière, la seconde paire réfléchissant une couleur sous ledit angle qui est identique à la couleur réfléchie par la première paire sous ledit angle et est sans ladite adaptation de couleur à tous les autres angles d'incidence.
27. Procédé selon la revendication 25, **caractérisé en outre en ce qu'il** comprend l'étape consistant à agencer les premier et second dispositifs optiques pour former un symbole qui est invisible sous ledit angle d'incidence et qui est visible sous les autres angles d'incidence.
